

How to measure relay protection time

Overview

A straightforward way of obtaining selective protection is to use time grading. The principle is to grade the operating times of the relays in such a way that the relay closest to the fault spot operates first. Calculate pickup values, timing curves, coordination time intervals (CTI), and test injection currents for overcurrent (50/51), differential (87), distance (21), and directional (67) protective relays. Accurately measuring the action time is a crucial step to ensure the reliability and. For successful protection coordination, relay working times must be accurately calculated since overcurrent relays activate when circuit current exceeds a predetermined threshold limit. The free online Time Overcurrent Relay Calculator lets electrical engineers immediately calculate relay operate. This calculator evaluates time-current coordination between two protective overcurrent relays — typically a downstream relay closer to the load and an upstream relay closer to the source — at a specified fault current level.
