

Why does PoE still need a switch

Overview

PoE switches provide a stable and reliable network experience through wired connections, avoiding the interference issues of wireless signals. They use dedicated pairs of wires to separately transmit power and data, ensuring that network performance is not affected by the power. A PoE switch is a special network switch that sends electricity and internet data through one regular Ethernet cable (like the ones you use for Wi-Fi or computers).) via Ethernet cables, enabling them to communicate over a Local Area Network (LAN). A Power over Ethernet switch both enables communication among network clients and provides power using the same RJ45 network cable to PoE-enabled edge devices, such as VoIP. While both serve the same basic function of connecting network devices, a PoE switch offers built-in Power over Ethernet (PoE) capabilities that can significantly simplify deployment and reduce costs in certain scenarios. It transfers data between them, manages traffic, and ensures that packets reach the right destination. A regular switch does only that: it.
